Acknowledgements

I am really grateful to Dr. Stefan Rüger, my supervisor for the project, to have proposed this subject. His guidance and valuable advice were particularly helpful to realise the thesis.

Moreover, I would like to thank the University of Technology of Compiègne for giving me the opportunity to study one year in Cranfield University. I would also like to thank Cranfield University for its facilities.

I would like to express my gratitude to M. Kazu Shimoda and Pr. Keiji Yanai of the University of Tokyo that made their datasets available and provided enlightenments and further details on their work.

Chapter 1

Introduction

Over the last few decades, the rate of obesity and overweight people in the World has greatly increased. As presented for the UK case in the figure 1.1, the obesity rate has increased by 12 % between 1980 and 2013, and by 13 % for the overweight rate. It is forecasted by the World Health Organisation to continue to grow.

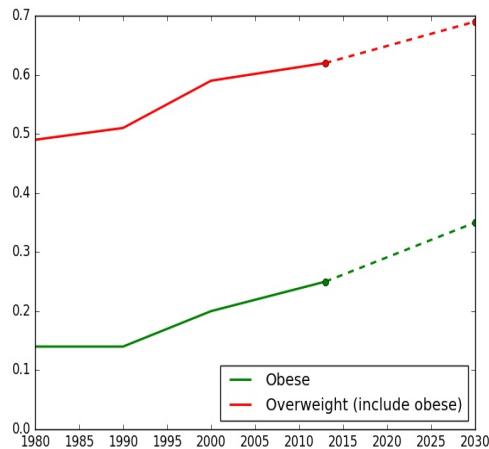

Figure 1.1: Obesity and overweight rate of the adult population in the uk between 1980 and 2030

Being “overweight” is defined as having a Body Mass Index (BMI) – a person’s weight

in kilograms divided by the square of his height in meters (kg/m^2) – of between 25 and 29.9, and “obese” by a BMI of 30 and above.

As stated in [1]), obesity is strongly associated with several major health risk factors such as stroke, high blood pressure, type 2 diabetes and high cholesterol. Thus, it has a great human and economic ([2] in 2010, 12 % of the total worldwide health expenditure is spent on diabetes and will continue to increase) cost for societies.

Associated with lifestyle changes, recording what we eat is one way to control our eating. Studies such as [3] show the benefit of reporting its daily diet to lose weight and improve the quality of its food intake. And more generally, it can be a way to treat eat disorders

Yet, manually recording detailed information regarding all meals is a tedious and time consuming task and it is hard for people to adhere to this process for a long time. Moreover, it often needs a trained patient and as presented in [4], users’ log are prone to errors (users tend to underestimate its intake).

At the same time, classification methods improvement of the classification methods. Imagenet is dataset containing more than 1,2 million images dataset split into 1000 classes. Since 2010, the yearly challenges include localization, classification and detection. Numerous researchers, students, educators or tech companies are participated.

As described in figure 1.2 and using figures from [5], the mean error for each class for classification and localization has been greatly reduced between 2010 and 2014.

With the widespread use of smartphone, cameras or wearable devices, people can easily take pictures of a good quality and are already taking photos of their food and posting them on website such as Food Gawker, Instagram, Flickr or Yelp.

That’s why, it has recently been proposed to automate it and assist patient and their medical personnel (nutritionist, psychologist) to understand the patient’s behaviour and habits. It extends the reach of care in a cost effective ways and counters some of the

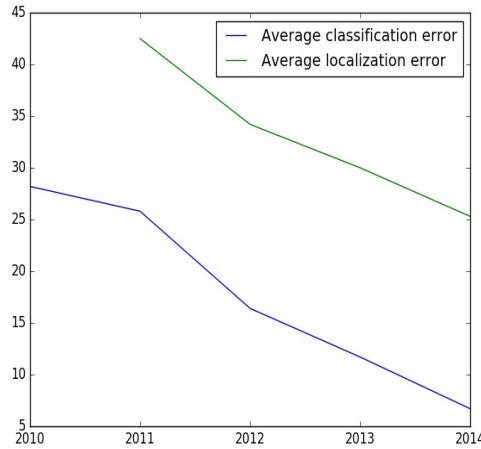

Figure 1.2: Average classification and localization error of the best results for different ImageNet challenges

previous problem of manual report. It's part of the rise of e-healthcare / m-healthcare [6, 7].

Users upload photographs of their daily meals to the application or website, and it constructs their food diary automatically. Using image processing, it determines the dietary composition of the meal and records the information for later viewing in formats such as a figure or a graphical representation.

Food recognition is a promising applications of image processing and machine learning. Its overall process is:

- Extract key characteristics
- Localise food items if the application allow multiple food items
- Recognise the food

Feature description is essential to achieve good object detection and image categorisation. Preferably the method should be invariant of the liminosity, orientation or scale of the picture.

In this thesis, we focus on the food recognition. It has already numerous challenges such as:

- **high intra-class variability** : we can have high variability between pictures for the same particular kind of food items, due to:
 - the environmental condition (e.g. luminosity, quality of the camera)
 - the way it is served
 - variation of the way the picture is taken: numerous transformation can be applied to a same picture (scale, translation, rotation, skewness)

This is illustrated in figure 1.3 for pictures of kaya toast.

- **low inter-class variability** : we can have low variability between different type of food such as between clear and miso soup as showed in 1.4.

This makes localisation, classification and retrieval of food images a difficult task for current state-of-the-art techniques, and hence a compelling challenge for image processing and machine learning researchers.

The organization of this thesis is as follow. In section 2, previous work on food localisation, recognition and intake estimation is reviewed. Section 3 introduces the different image descriptors used, and in section 4 the classifiers are presented. In section 5, the dataset is introduced. Section 7 reports the experimental settings and results. Finally, in section 8, we draw the conclusion and state the limitation and possible future work.

Chapter 2

Previous work

2.1 Food localization

A way to localize food is based on edge detection and color segmentation.

In [8], the authors describes and compare these two methods to localise an orange in a picture. It applied these methods on a small dataset of 20 orange images (only one orange per image), with different lighting conditions and backgrounds (pictures are taken from the Internet). In more details, the edge-based segmentation apply the canny-edge segmentation, then apply non-maximum suppression to eliminate noises. Then, each pixels are classified. The colour-based segmentation normalised the lightning condition with a gaussian low-pass filter, convert the RGB image into a $L*a*b$

1. gaussian low pass filter to normalize the lightning condition
2. convert the image from RGB representation to $L*a*b$
3. use the a channel to classify each pixel as “fruit” or “non-fruit”
4. remove small object

5. fill the binary image regions and holes

For orange detection, the color segmentation has an higher accuracy. Yet, it is very hard to generalise this method.

An other method for food detection relies on circle detection. Indeed, food items are often served in a round shape container such as a bowl, a pan or a plate.

In [9], the authors describe their use of the Hough transformation to detect circle (they constitutes the food region).

2.2 Food recognition

Food recognition

Using SVM:

Local using BOW: 3.3 global feature: Color and texture description: Spatial pyramid:

Mix of several features:

In [10], the authors develop a mobile application to keep food records of a user that is taking pictures of one's meal. Their method can detect multiple food items in one picture. They use a color marker as an illumination and size indicator.

When the user upload a picture, it is segmented, then classified by a backend server. The estimation are sent back to the user for confirmation.

Their method is named "multiple hypotheses segmentation and classification (MHSC)".

It is an iterative method composed of a segmentation, description (extraction of features) and classification step.

For segmentation, the authors first detect salient region, using Canny edge and color distribution to reject background. Then, they apply a multiscale segmentation using normalized cut. Small segmented regions are discarded.

On the selected region, the authors used a mixed of global descriptors (first and second moment of each channel for RGB, YCbCr, L*a*b*, and HSV color spaces, first and second moment of the entropy in RGB, predominant color describtor, entropy and two first moments of the Gradient Orientation Spatial-Dependence Matrix, entropy categorization and fractal dimension estimation and estimation of the fractal dimension of the response of different gabor filter) with local feature (multi Bag-Of-Words using SIFT for RGB, SURF for RGB, SIFT for each channel of the RGB representation and steerable filters).

Each of the 12 descriptor, global and local, is classified independantly and assigned a confidence score. A late fusion function (either maximum confidence score or majority vote) is used to decide the final class. For clasification, the authors use K-NN and SVM.

If the total score is inferior to a certain threshold, the overral process is repeated. The confidence score of the previous step is used to improve the segmentation.

Applied on a dataset composed of 83 labels (79 food classes plus “utensils”, “glasses”, “plates”, and “plastic cups” classes), each class having at least 30 images, they obtain a top-8 accuracy of 75 %, using K-NN with the maximum confidence score.

More recently, people have started to heavily use Convolutional Neural Networks *CNN* with great results.

In [11], the authors use a pre-trained Deep CNN *DCNN* for feature extraction. The DCNN, nammed OverFeat,¹ was trained on ImageNet and is composed of 19 layers. The authors add more conventional image features to obtain feature vectors composed of:

1. a variant of the Histogram of Oriented Gradients *HOG* called “RootHog” that is an element-wise square root of the L1 normalized HOG
2. mean and variance values of each channel of the RGB representation value of pixels from each of 2*2 block

¹Can be found <http://cilvr.nyu.edu/doku.php?id=code:start>

3. the last two layers of the DCNN

The three descriptors are then encoded in a fisher vector. Using SVM, the authors obtain 72% of accuracy for UEC-FOOD 100.

[12] use a fine-tuned DCNN, pre-trained on 2000 classes (including 1000 food classes) from ImageNet. The authors obtain 78 % accuracy on UEC-FOOD 100 and 68 % for UEC-FOOD 256. This dataset, presented in [13], is an extension of 256 classes of UEC-FOOD 100 using a so-called “foodness classifier” and transfer learning on images coming from crowdsourcing. In [14], the authors use a pre-trained DCNN on UEC-FOOD 256.

2.3 Food intake estimation

FoodLog² is a website that enables the user to upload pictures of its daily meals to be archived and processed. The goal of this application is to assist the user to keep notes of their meals and balance the nutritional values coming from different kinds of food.

In [15], the images containing food items are identified by exploiting features related to the HSV and RGB colour domains, as well as the shape of the plate. A SVM classifier is trained to detect food images. More specifically, the images are divided in 300 blocks and each block is classified as “non-food” (discarded block) or one of the nutritional categories described in the “MyPyramid” model³.

MyPyramid [16] was designed by the United State Departement of Agriculture *USDA* in 2005 and was replaced in 2011 by “MyPlate”⁴ [17]. This dietary model is composed of 5 kinds of food: grains, vegetable, meals and beans, milk and fruit. For each group, a recommended intake per day is associated, Fig. 2.1. Quantity is categorized by “servings” *SV*, making it simpler to compute and keep log.

²<http://www.foodlog.jp>

³<http://www.mypyramid.gov>

⁴<http://www.choosemyplate.gov>

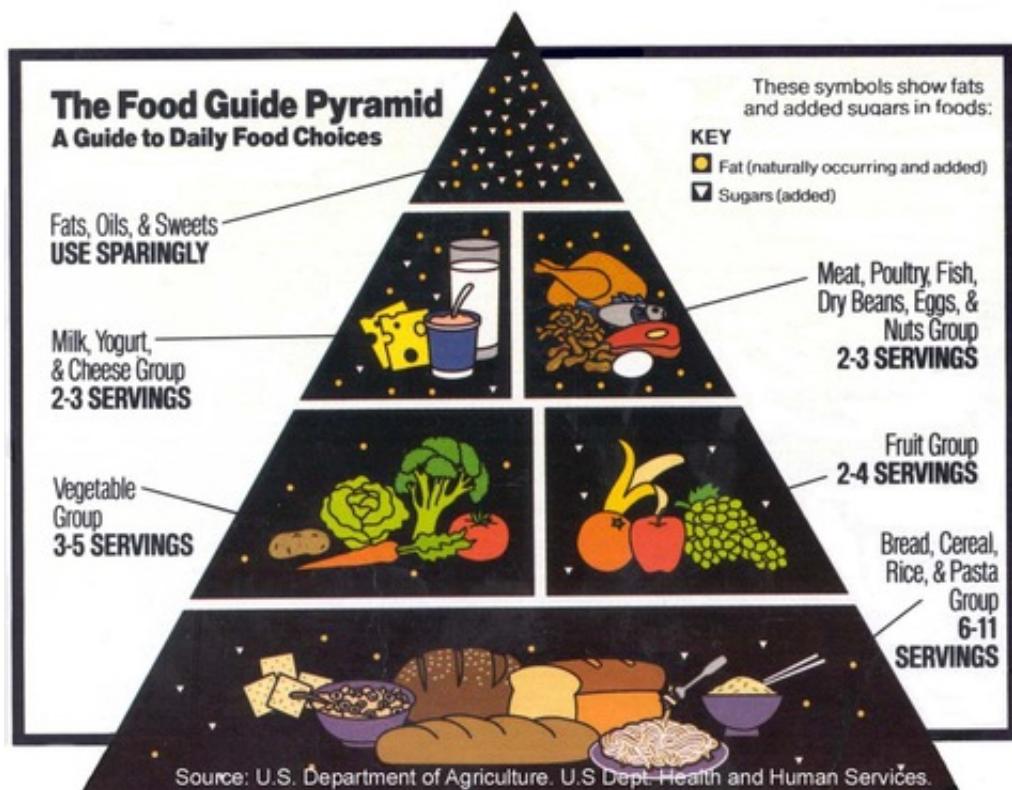

Figure 2.1: USDA MyPyramid original logo

In [18] the Support Vector Machine is replaced by a Bayesian Framework *BF*. The *BF* is based on the Gaussian Naive Bayesian (suppose independence between every pair of features and the distribution of each feature is assumed to be Gaussian). The *BF* takes into account the estimation using color moments and Bag-Of-Feature of SIFT, the prior distribution and the mealtime category (breakfast, lunch and dinner).

In [19], the authors use a Convolutional Neural Network [CNN] to detect and classify food from a small subset of image loaded in the FoodLog system. Compared to the other conventional methods (use of a feature descriptor such as Bag-of-Words with a classifier, e.g. SVM) described previously, the CNN showed a significantly higher accuracy.

An other method to estimate the food intake is to evaluate the food volume.

In [20], the authors presents a method that use the depth information of the picture. Once the food has been classified, the area of the food container (bowl, plate) and the depth value of the contained food is computed to obtain the food volume. Yet, this technique is still limited as it can only be used for non-transparent food, i.e it can't detect some food item such as water or cooked rice, and force the user to have a depth camera (such as Kinect).

In [21], the authors presents a novel food recognition system that is able to estimate of the nutrition intake. Moreover, they develop a mobile application to easily take pictures and keep track of the user's diet. To measure the food intake, authors compare before and after eating pictures and use the thumb as the calibration system (it supposes a one-time calibration to know the size of the thumb of the user). The process to show the intake is:

1. the user takes food pictures
2. get the contour of each picture
3. recognition of the food using color, shape and size features with SVM.

4. volume calculation, that is computed in two steps:
 - (a) user takes a picture from above. Then, the food shape is divided into known shape (rectangle, circle, triangle ...) to compute the area.
 - (b) user takes a second picture from the side. This is used to compute the height of the food and calculate the overall volume.

The system assumes that the plate is white and round.

5. use a nutrition database to obtain the average calories

If the user hasn't eaten everything, the entire must be repeated. The drawbacks of this method is the user have to take several pictures, with one's thumb each time and it has been tested with a limited set of simple food types.

In [22], the authors propose a food recognition system named **FoodCam** to identify food items of a picture. The presented process is used on a mobile application, the user taking a picture that is transferred to a sever, processed and results are displayed.

The first step is to detect potential region with multiple object detection algorithms. Then, for these regions, several feeatures are extracted and used to feed SVM with Multiple Kernel Learning *MKL* method. To detect candidate regions, the authors use:

- Felzenszwalb's deformable part model (DPM), based on Histogram of Oriented Gradients (HOG).
- a circle detector: the image is converted to a gray-scale, contour are extracted using the Canny Edge Detector and circles detected by the Hough Transform
- JSEG region segmentation: segmente region based on color. It only keeps circular regions.
- whole image, for picture with one large dish

Then, it aggregates all the candidate regions to get the bounding box of each food item.

For each region, it extracts multiple common features:

- Bag of Feature of SIFT and C-SIFT (sift with color invariant characteristics)
- Spatial pyramid representation: object regions are divided by hierarchical grids. In this paper, the three level pyramid is used: 1×1 , 2×2 , 3×3 . For each grid, a BoF vector is extracted
- Histogram of Oriented Gradient (HOG)
- Gabor texture

After extraction of the feature vectors from each candidate region, a linear SVM trained by MKL is used (χ^2 kernel).

For evaluation, the authors build a new dataset composed of 100 categories of traditional Japanese dishes with their associated bounding boxes for a total of 9060 images named **UEC-FOOD 100**. For multiple food item images, they obtain 55.8 % classification rate and 68.9 % for single food item pictures.

In [23], the authors develop a mobile real-time food recognition system for calorie and nutrition estimation. Contrary to the previous paper, all the calculation are realised on the user smartphone. The recognition takes less than 1 second thanks to the multi-core architecture of modern smartphones. The user takes a picture and draws bounding boxes around food items. Then, the system refines the segmentation based on the users' rough demarcation using Grabcut, an iterative method using graph cuts to extract foreground. For each item, it extracts image features and classifies the image among the one hundred food classes using a linear SVM. Then, the top five food candidates are shown and the user can select one of the propositions. This recognition is updated every one second, the direction arrow as presented in figure 2.2 being displayed to help the user improve

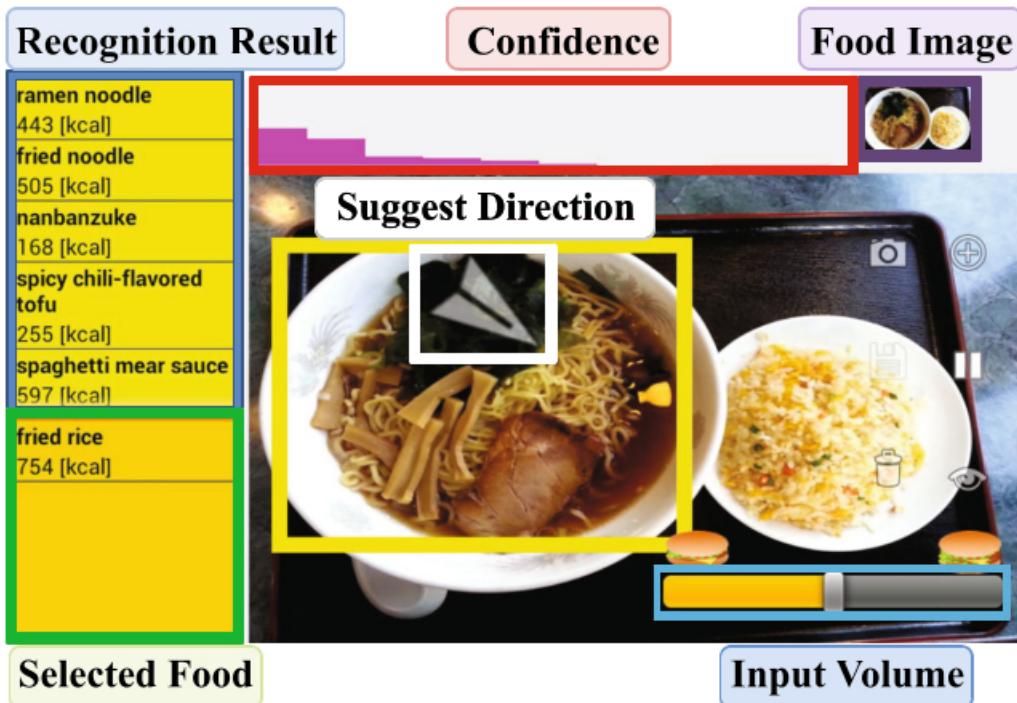

Figure 2.2: Annotated screenshot of the FoodCam application

the result by changing the camera position and direction. To estimate the most suitable direction, the authors use the Efficient Sub-window Search method, a recent and powerful window search algorithm used in object detection. The mobile application keep records of all the pictures and their approved classification and labeled with the volume estimation. Food intake is estimated thanks to a slider on the bottom-left of the screen.

Two different descriptors are used:

- bag-of-feature with SURF and color histogram with the χ^2 kernel feature map
- HOG and a color patch descriptor (mean and variance of RGB values on a 2×2 blocks of pixel) encoded using Fisher Victor, a patch encoding strategy using Gaussian mixture models.

The authors evaluate these two methods on a UEC-FOOD 100. Taking the top 5 classes, they obtain 79 % classification accuracy for color patches and 68 % for the other.

Chapter 3

Feature descriptor

For a computer, a picture is represented as a 2-D or 3-D array. To facilitate the classification, feature descriptor extract derived values (the features), calculated to be more informative and invariant to some common picture transformation.

As such, colour is one of the key components of a food item, thus it is widely applied for classification. Color statistics are commonly used, such as the first and second moment values for different channels. It can be computed for multiple color representations (RGB, HSV, gray, YCrCb or L*a*b* space).

Another import feature of food is the texture. Numerous texture descriptors can be used such as Gabor filters or Local Binary Pattern.

3.1 Local binary pattern

Local binary pattern is a visual descriptor for texture composition of an image, first presented in 2002 in [24] (although the concept of LBPs were introduced as early as 1993).

3.1.1 Gray-scale LBP

The figure 3.1 represents an example of the LBP in which the LBP code of the center pixel (in red color and value 20) is used as a local intensity threshold : the neighbour pixels whose intensities are equal or higher than the center pixel's are labeled as "1"; otherwise as "0". Then, starting always from the same point, we can transform this binary string to decimal and is used to describe the central pixel. In this example we start at the top-right point and work our way clockwise accumulating the binary string as we go along and obtain the value 24.

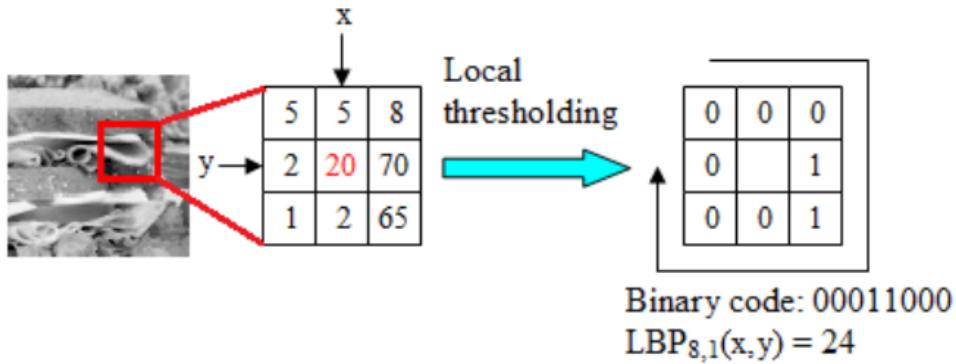

Figure 3.1: Illustration of the LBP descriptor's process

We adopt the following notation. Given a pixel $c = (x_c, y_c)$, the value of the *LBP* code of c is defined as:

$$LBP_{P,R}(x_c, y_c) = \sum_{p=0}^{P-1} s(g_p - g_c) 2^p$$

where:

- p is a neighbour pixel of c and the distance from p to c does not exceed R . Thus, R is the radius of a circle centered in c and P is the numbered of sampled points.
- g_p and g_c are the gray values (intensities) of p and c

- $s(x)$ is the function defined as:

$$s(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{otherwise} \end{cases} \quad (3.1)$$

In Fig. 3.1, R and P are 1 and 8 respectively.

The number of histograms bins for $LBP_{P,R}$ is 2^P .

3.1.2 Uniform LBP

This algorithm has been enhanced to make it rotation invariant. Still in [24], the authors introduce the notion of uniform LBP. A LBP is considered to be uniform if it has at most two bitwise transitions (0 to 1 or 1 to 0 transitions in the binary word).

For example, the pattern *01000000* (2 transitions) and *11111110* (1 transition) are both considered to be uniform. For a $LBP_{P,R}$, there is $p + 1$ possible uniforms.

Non-uniform LBP are considered as noise and are assigned the same constant value.

Thus, for uniform LBP, we use the formula:

$$LBP_{P,R}^{uni}(x_c, y_c) = \begin{cases} \sum_{p=0}^{P-1} s(g_p - g_c) 2^p & \text{if uniform} \\ P + 1 & \text{otherwise} \end{cases}$$

3.2 Color descriptor

3.2.1 Color histogram

HSV space is composed of:

- **Hue channel:** represents the dominant spectral component—color in its pure form,

as in green, red, or yellow

- **Saturation** channel: represents the white added to the pure color (the Hue)
- **Value** channel: represents the brightness of the color

Hue and Saturation corresponds to the chromaticity of the colour. For the joint histogram (2D histogram), the H and S channels are used as value is dependant of the condition where the picture were taken, thus is not interesting.

The coordinate system is cylindrical, and is often represented by a subspace defined by a six-sided inverted pyramid. The top of the pyramid corresponds to, with the “white” at the center. The hue is measured by the angle around the vertical axis, with red corresponding to 0. The saturation ranges from 0 at the center to 1 on the surface of the pyramid. An inverted cone is also used to denote the subspace instead of the pyramid.

3.2.2 Color moments

3.2.3 The first two moments

For a discrete random variable X , the first two moments are defined as:

- **Expected value:**

$$\mathbb{E}[X] = \mu = \sum_{i=1}^n p_i x_i$$

- **Variance:**

$$\text{Var}(X) = \mathbb{E}[(X - \mathbb{E}[X])^2] = \sum_{i=1}^n p_i(x_i - \mu)^2$$

3.2.4 Hu moments

Raw moments

For a two-dimensional continuous function $f(x,y)$ the moment (sometimes called “raw moment”) of $(p + q)$ th order is defined as:

$$M_{pq} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x^p y^q f(x,y) dx dy$$

for p and $q \in \mathbb{N}$.

Central moments

And the central moments are :

$$\mu_{pq} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - \bar{x})^p (y - \bar{y})^q f(x,y) dx dy$$

with $\bar{x} = \frac{M_{10}}{M_{00}}$ and $\bar{y} = \frac{M_{01}}{M_{00}}$

Normalized central moments

The normalized central moments are:

$$\eta_{ij} = \frac{\mu_{ij}}{\mu_{00}^{\gamma}}$$

where $\gamma = 1 + \frac{i+j}{2}$ for $i + j \geq 2$.

Definition of the Hu moments

On the base of those Moments, Hu in [25] introduced 7 Moments which are invariant for translation, rotation and resizing:

$$I_1 = \eta_{20} + \eta_{02}$$

$$I_2 = (\eta_{20} - \eta_{02})^2 + 4\eta_{11}^2$$

$$I_3 = (\eta_{30} - 3\eta_{12})^2 + (3\eta_{21} - \eta_{03})^2$$

$$I_4 = (\eta_{30} + \eta_{12})^2 + (\eta_{21} + \eta_{03})^2$$

$$I_5 = (\eta_{30} - 3\eta_{12})(\eta_{30} + \eta_{12})[(\eta_{30} + \eta_{12})^2 - 3(\eta_{21} + \eta_{03})^2]$$

$$+ (3\eta_{21} - \eta_{03})(\eta_{21} + \eta_{03})[3(\eta_{30} + \eta_{12})^2 - (\eta_{21} + \eta_{03})^2]$$

$$I_6 = (\eta_{20} - \eta_{02})[(\eta_{30} + \eta_{12})^2 - (\eta_{21} + \eta_{03})^2] + 4\eta_{11}(\eta_{30} + \eta_{12})(\eta_{21} + \eta_{03})$$

$$I_7 = (3\eta_{21} - \eta_{03})(\eta_{30} + \eta_{12})[(\eta_{30} + \eta_{12})^2 - 3(\eta_{21} + \eta_{03})^2]$$

$$- (\eta_{30} - 3\eta_{12})(\eta_{21} + \eta_{03})[3(\eta_{30} + \eta_{12})^2 - (\eta_{21} + \eta_{03})^2]$$

3.3 Bag-of-Words

3.3.1 Process

Bag-of-Words *BoW*, also called Bag of features, is a feature descriptor method inspired by information retrieval from textual documents.

As illustrated in Fig. 3.2, the main steps are:

- On each picture, keypoints are detected. In my case, I use a dense grid of evenly spaced points at a fixed scale and orientation.

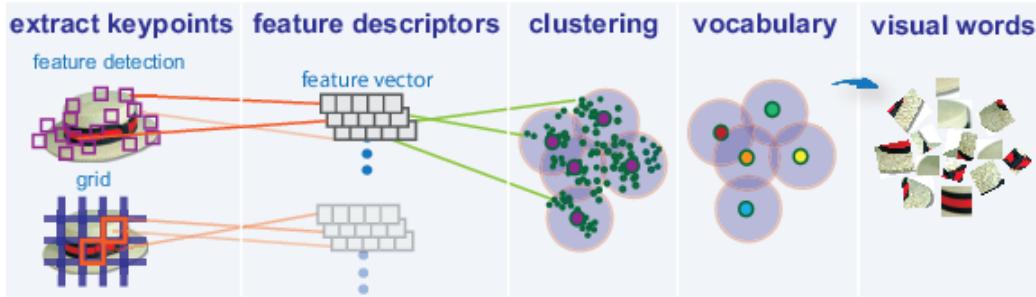

Figure 3.2: Illustration of the Bag-Of-Visual-Words model

- For every keypoint, a feature vector is generated. we describe it, SIFT (scale invariant feature transform).
- We generate the fix number of visual words that compose our codebook.
- We express each image as an histogram of these words' appearance.

The combination of a dense grid and SIFT is commonly called dense SIFT. It has been showed to have greater accuracy than using SIFT for keypoint detection and description.

3.3.2 SIFT descriptor

A SIFT descriptor of a local region (keypoint) is a 3-D spatial histogram of the image gradients as presented in the figure 3.3. The gradient at each pixel is regarded as a sample of a three-dimensional elementary feature vector, formed by the pixel location and the gradient orientation. Samples are weighed by the gradient norm and accumulated in a 3-D histogram h , which (up to normalization and clamping) forms the SIFT descriptor of the region. An additional Gaussian weighting function is applied to give less importance to gradients farther away from the keypoint center.

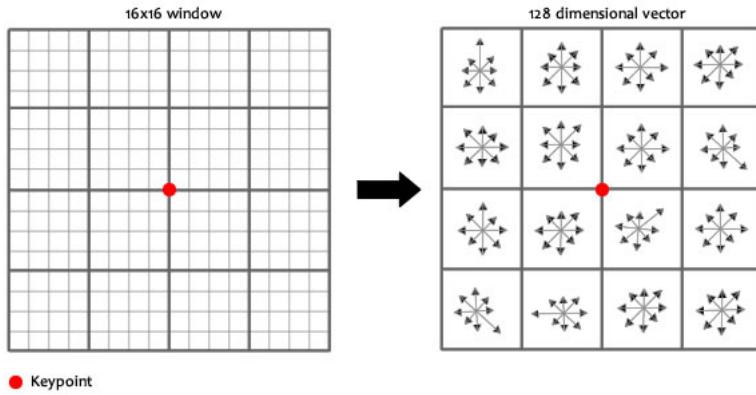

Figure 3.3: Illustration of SIFT as a local image descriptor

3.3.3 K-mean clustering

Given a set of observations (x_1, x_2, \dots, x_n) , where each observation is a d-dimensional real vector, k-means clustering aims to partition the n observations into k ($k \leq n$) sets $S = S_1, S_2, \dots, S_k$ so as to minimize the within-cluster sum of squares (sum of distance functions of each point in the cluster to the K center). In other words, its objective is to find:

$$\arg \min_S \sum_{i=1}^k \sum_{x \in S_i} \|x - \mu_i\|^2 \quad (3.2)$$

Problem, the exact solution is a NP hard problem. That's why, we can use Lloyd's heuristic algorithm to compute an estimation.

It is an iterative method that find a local minima of the Eq. 3.2:

1. A set of k initial “means” is chosen randomly within the data domain $M = \{m_1, m_2, \dots, m_k\}$
2. Then, k clusters are created by associating every observation with the nearest mean.

$$\forall i \in \{1, \dots, k\}, \quad S_i^{(t)} = \{x_p : \|x_p - m_i^{(t)}\|^2 \leq \|x_p - m_j^{(t)}\|^2 \quad \forall j \in \{1, \dots, k\}\}$$

3. The centroid of each of the k clusters becomes the new mean.

$$\forall i \in \{1, \dots, k\}, m_i^{(t+1)} = \frac{1}{|S_i^{(t)}|} \sum_{x_j \in S_i^{(t)}} x_j$$

4. Repeats step 2 and 3 until M not longer changes.

The centroid results and number of iterations are highly dependant of the initial centroid.

As a result, the computation is often done several times, with different initializations of the centroids. One method to help address this issue is the k-means++ initialization scheme, which has been described in [26]. This initializes the centroids to be (generally) distant from each other, leading to provably better results than random initialization.

Chapter 4

Classifier

4.1 Decision tree and random forest

Decision tree is a simple learning method that can be used for classification or regression. The implementation used of decision tree is based on the CART (Classification and Regression Tree) algorithm.

A decision tree is recursively partitioning the space in a left P_{left} and right P_{right} partitions such that the samples with the same labels are grouped together, i.e. the generated sets with the smallest impurity.

It continues to split until the impurity can't be reduced or some pre-set stopping rules are met. Alternatively, the data are split as much as possible and then the tree is later pruned.

Since the set of splitting rules used to segment the predictor space can be summarized in a tree, these types of approaches are known as decision tree methods. The figure 4.1 illustrate a toy example of decision tree.

The most used impurity measure's functions are:

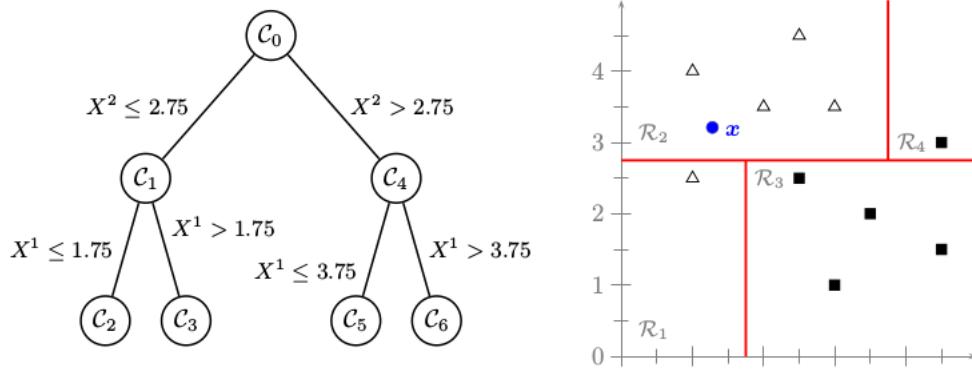

Figure 4.1: Decision tree of depth two for ten elements (X^1, X^2) belonging to the black square and white triangle classes

- **Gini:**

$$H(X_m) = \sum_k p_{mk}(1 - p_{mk})$$

- **Cross-entropy:**

$$H(X_m) = -\sum_k p_{mk} \log(p_{mk})$$

To avoid overfitting, keep the decision tree as simple as possible.

Random forest or Decision forest is build from a number of decision trees. The prediction of the ensemble is given as the averaged prediction of the individual classifiers. Each tree is trained on a random subsets of the training data.

When building these decision trees, each time a split in a tree is considered, a random sample of m predictors is chosen as split candidates from the full set of n features. A typical value of m is $m \approx \sqrt{n}$.

4.2 Support Vector Machine

(binary case) + kernel trick + multi-class (one-versus-one or one-versus-all)

Support Vector Machine SVM is a method used for classification and regression.

4.2.1 Linear SVM

Hard margin

A support vector machine constructs a hyper-plane or set of hyper-planes in a high or infinite dimensional space. Intuitively, a good separation is achieved by the hyper-plane that has the largest distance to the nearest training data points of any class (so-called functional margin), since in general the larger the margin the lower the generalization error of the classifier.

For a 2 classes (value represented as -1 and 1), the hyperplane must verify:

$$\vec{x}_i \cdot \vec{w} + b \geq +1 \text{ for } y_i = +1 \quad (4.1)$$

$$\vec{x}_i \cdot \vec{w} + b \leq -1 \text{ for } y_i = -1 \quad (4.2)$$

where \vec{w} is the normal to the hyperplane

Combining equation 4.1 and 4.2, we obtain:

$$\forall i \in 0, \dots, n, \quad y_i(\vec{x}_i \cdot \vec{w} + b) - 1 \geq 0$$

where $y_i = f(\vec{x}_i) = -1, 1$

Gemetrically, the distance between the two hyperplane from 4.1 and 4.2 is $\frac{2}{\|\vec{w}\|}$ (equal width to each side).

Thus, to obtain the hyperplane with the highest margin, we want to maximize:

$$\arg \max_{\vec{w}, b} \frac{2}{\|\vec{w}\|^2}$$

which is equivalent to minimize:

$$\arg \min_{\vec{w}, b} \frac{1}{2} \|\vec{w}\|^2$$

Thus, we obtain a constrained optimization problem.

Soft Margin

For the case of non-separable training sets, we introduce a penalty parameter C , $C \leq 0$ and obtain:

$$\arg \min_{\vec{w}, b, \zeta} \frac{1}{2} \|\vec{w}\|^2 + C \sum_{i=1}^n \zeta_i \text{ subject to } y_i(\vec{x}_i \cdot \vec{w} + b) \geq 1 - \zeta_i, \zeta_i \geq 0, \forall i \in [1, \dots, n]$$

The decision function for new example is:

$$f(\vec{x}) = \text{sign} \left(\sum_{s_i \in \text{support vectors}} w_i \vec{s}_i \cdot \vec{x} + b \right)$$

where the support vectors selected sub-set of the training examples that define the boundary of the hyperplane separation and hence the classification boundary.

To generalize SVM to the case of multi-class, multiple approaches are possible:

- “one-versus-one”: train a separate classifier for each different pair of labels. This leads to $\frac{N(N-1)}{2}$ classifiers
- “one-versus-all”: train a single classifier per class, with the samples of that class as positive samples and all other samples as negatives

4.2.2 Non-linear SVM and kernel trick

The idea of the kernel trick is to transform the initial space to a higher dimensional space where a hyperplane can separate this data. Kernel trick: use kernel function to implicitly transform datasets to a higher-dimensional using no extra memory, and with a minimal effect on computation time: realise just a dot product.

To use the linear SVM for non-linear data: project the data in a new feature H space thanks to an application and then research for maximum margin hyperplane in H to make sure that the new problem has a unique solution, must satisfy the Mercer's condition or simply it must be a positive-definite matrix

- **Linear** : $k(x, y) = \langle \vec{x}, \vec{y} \rangle + C = x^T y + C$
- **Polynomial**: $k(x, y) = (\gamma \cdot \langle \vec{x}, \vec{y} \rangle + C)^d = (\gamma \times x^T y + C)^d$
- **Radial Basis Function (RBF)**: $k(x, y) = \exp(-\gamma \|x - y\|^2)$
- **Chi-Square**: $k(x, y) = 1 - \sum_{i=1}^n \frac{(x_i - y_i)^2}{\frac{1}{2}(x_i + y_i)}$

A modified version presented in [27] of this kernel is the **Additive Chi-Square**

$$\text{kernel} : k(x, y) = \sum_{i=1}^n \frac{2(x_i - y_i)}{x_i + y_i}$$

The adjustable parameters of these kernels are d , γ , C and must be chosen according to the problem.

For food classification, the chi square kernel is the most used kernel as it is often combined with histograms. !!CITE!!

4.3 Convolutional neural network

A **Convolutional Neural Network CNN** is a variant of a Neural Network, mainly used for machine learning on pictures. It is inspired by the neural system composed of different

layers (made up of multiple neurons) and communication schemes.

Each neuron receives some inputs, performs a dot product and optionally follows it with a non-linearity function. The whole network still expresses a single differentiable score function (linear or not): from the raw image pixels (the input layer) to class scores (output layer). Hidden layers separates these two layers, as described in 4.2.

A CNN (and more generally a NN) is trained by backpropagation, applying gradient descent that will update the weights.

It is a powerful, adaptive and noise resilient pattern recognition. The training phase is rather slow but querying it with an unseen example is fairly fast.

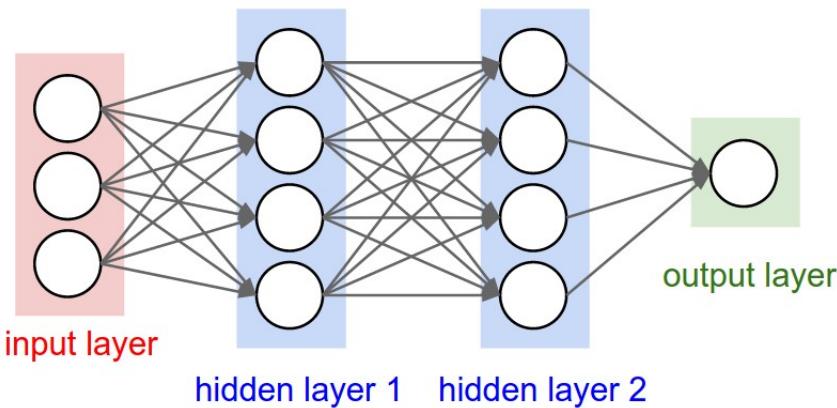

Figure 4.2: A regular 3-layer neural network

The figure 4.3 is a simple CNN based on the VGG-NET structure. It is composed of the 4 most popular layers that can be found in a CNN:

- **Convolutional** : layer giving the name for this type of neural network. It convolves the input image with a set of learnable filters, each producing one feature map in the output image, i.e. it computes a dot product on a neighborhood of pixels:

$$y_{i,j} = b + \sum_{l=0}^{n-1} \sum_{m=0}^{n-1} w_{l,m} x_{j+l, k+m}$$

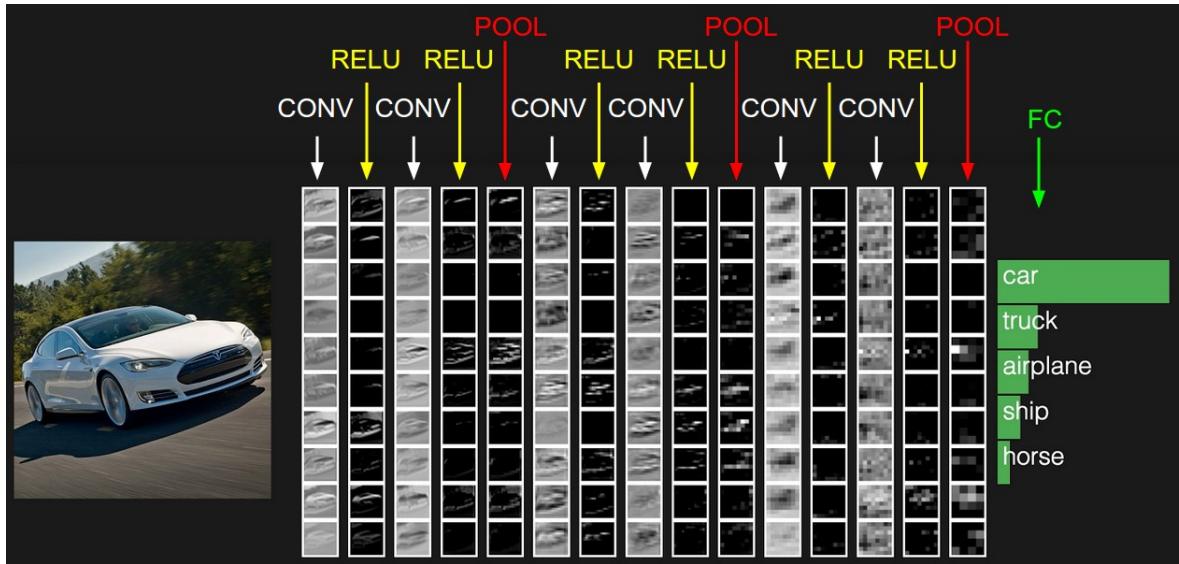

Figure 4.3: Example of a 16-layer deep convolutional neural network. The input layer is a whole picture, the output layer is the probability for each possible class. It used a succession of Convolutional, ReLU, Pooling layer with a final Fully connected one.

with:

- $x_{i,j}$ the input activation at position (x, y)
- $w_{l,m}$ the weights of the neuron
- $n \times n$ is the size of the layer
- b is the bias value
- $y_{i,j}$ the output values of the j , k th neuron

- **Activation layer:** element wise operation.

Example of function: the **Rectified Linear Unit *ReLU*** defines as:

$$f(x) = \max(0, x)$$

- **Pooling** or subsampling layer: down sampling of the input activation size. It re-

duces the number of values between the input and the output values of this layer to avoid overfitting the data and reduce the computation time of the neural network.

The most common downsampling operation is max, giving rise to **max pooling**, here shown with a stride of 2 in figure 4.4.

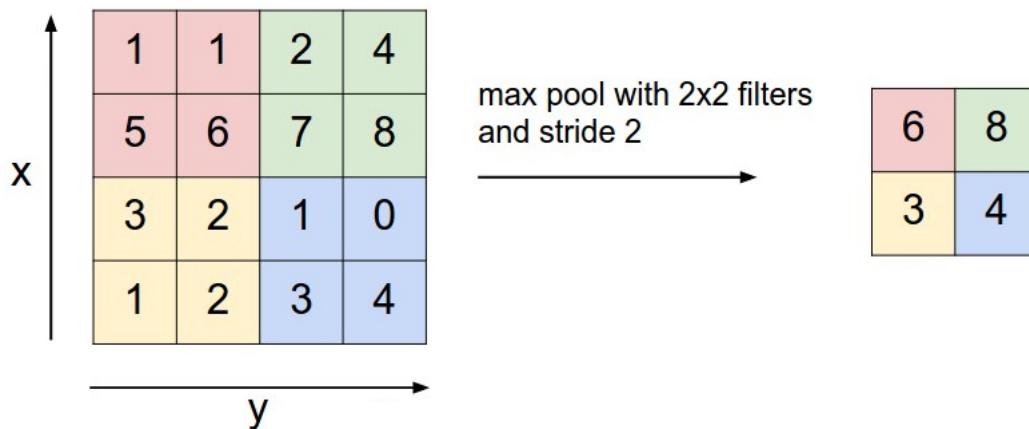

Figure 4.4: Illustration of a max pooling layer of stride 2, i.e. it selects the maximum value from a 2×2 square

- **Fully connected:** compute the class scores. As the name implied, this neuron is connected to all activations from the previous values. For classification, it corresponds to a loss function, a common one is the sigmoid:

$$\sigma(x) = \frac{1}{1 + \exp(-x)}$$

A CNN can also be used as a feature descriptor if we use the output of the last layers.

Chapter 5

Dataset

Why do we use a dataset? - learning - some research make them freely available to test

Describe how it was build ?

5.1 Choice of the dataset

Numerous datasets are already existing and have been made freely available. I could create my own dataset but it would have been very time consuming and I wouldn't be able to compare my results with previous scientific papers.

To choose, a couple of criteria were defined:

- Preferably, it should be a recent dataset
- It must have a decent number of pictures (a few thousand pictures)
- It must be composed of a general kind of food such as worldwide, Western or Asian
- It must contain pictures with multi-food items

As we can see in the table 5.1, UEC FOOD 256 is the dataset that best match our expectations.

Name	Re-lease date	Number of pictures	Type of food	Number of classes	Multiple food items
PFID [28]	2009	4545	American fast-food	101	No
UEC FOOD 100 [22]	2012	14361	Japanese	100	Yes
FIDS 30 [29]	2013	971	Fruit	30	No
ETHZ Food-101 [30]	2014	101 000	European	100	No
UPMC Food-101* [31]	2015	90 840	European	100	No
UNICT-FD889 [32]	2015	3 583	World	889	No
FooDD [33]	2015	3000	Fruit	23	Yes
UEC FOOD 256 [13]	2015	31395	World	256	Yes

Table 5.1: Summary of some available food datasets according to the criteria.

*UPMC FOOD 101 is including the recipe for most of the pictures

5.2 UEC FOOD-100 and UEC FOOD-256

UEC FOOD-100 and **UEC FOOD-256** are datasets used for food localization and recognition.

The UEC FOOD-100 dataset can be found in ¹. It was created in 2012 and presented in [22].

It contains 100 types of food, mainly Japanese food. Each kind is represented by at least 100 samples.

As presented in figure 5.1, a photo can contain more than one food items. The dataset contains files to indicate bounding boxes marking the location of a food items.

UEC FOOD-256 can be found in ². It was presented in [13] in 2015. It contains the 100 types of food from UEC FOOD-100 plus 156 new ones. The pictures have been automatically extracted from the Internet and pre-processed.

The newly introduced food kinds are more international dishes with food from various

¹Dataset can be found at <http://foodcam.mobi/dataset100.html>

²Dataset can be found at <http://foodcam.mobi/dataset256.html>

countries such as France, Italy, the USA, China, Thailand, Vietnam, Japan and Indonesia.

As for FOOD 100, every food photo has a bounding box indicating the location of the food item.

The most represented category is miso soup with 728 and rice with 620 pictures.

Figure 5.1: Pictures with multiple food items from UEC FOOD 256

Chapter 6

Methodology

As illustrated in Fig. 6.1, we have our initial dataset that we split in :

- a **validation set** (10 % of the dataset) used for hyper-parameter optimization or model selection for localisation and classification
- a **train / test set** (remaining dataset) used for the localisation and classification. The train set is used to learn the parameters of a classifier that is then evaluated on the test set (using the same dataset for learning and testing would be a methodological mistake as it would overfit the dataset)

6.1 Hyperparameter optimization

There are numerous parameters that are part of the machine learning but are not learnt. Typical example include which kernel function used (if any) or the value of the penalty parameter C for SVM, the number of k of neighborhoods for kNN.

We use the exhaustive grid search method to select the parameters that have the highest performance score through 10 fold cross validation. It generates all the possible combi-

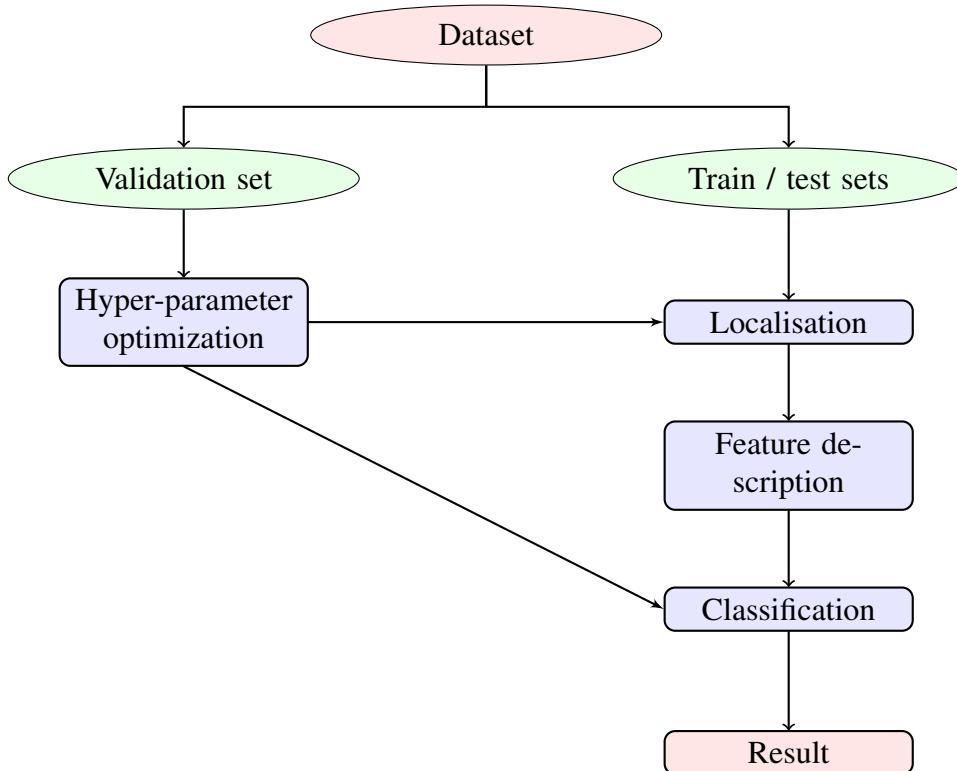

Figure 6.1: General process of the localisation and classification

nation of parameters value and train / test the classifier.

6.2 Localisation

For localisation, a different approach from the litterature has been used. The usual way is to detect area of food and non food in a picture. Yet, it was noticed that the food items of UEC FOOD 256 and 100 tends to be in the middle and stands out. Moreover, demanding the user to take pictures that follow these charastetcs is reasonable.

That's why a pre-trained CNN used for saliency detection has been used. It has been pre-trained in [34] on multiple datasets (Multi-Salient-Object, ILSVRC14). It is available

¹.

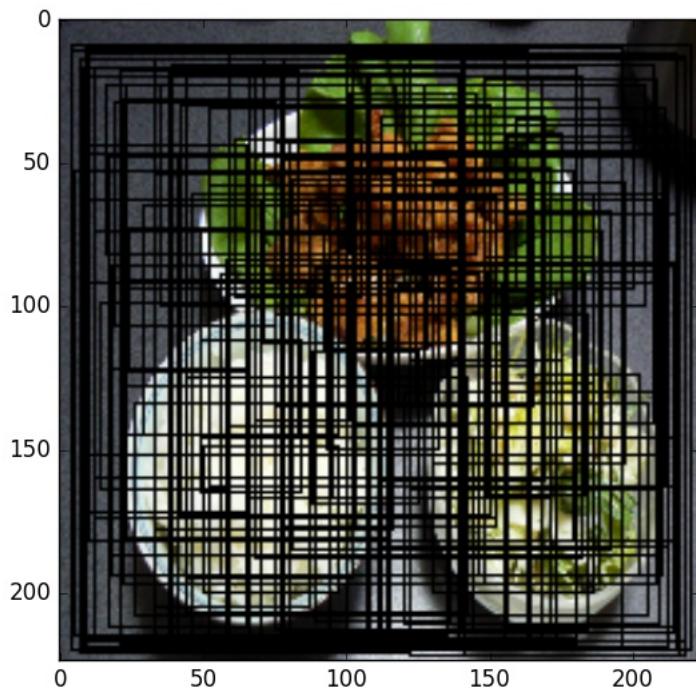

Figure 6.2: Picture of the 100 possible bounding boxes that the salient CNN will try to recognise

The CNN structure is a copy of “GoogleNet” model [35], i.e. it is composed of 22 layers, corresponding to a succession of convolutional, max pooling and activation layers, the last one being a sigmoid function.

The CNN has been pre-trained to detect the likelihood to belong to one of the 100 arbitrary bounding boxes as presented in Fig. 6.2.

Bounding boxes with a probability higher than a threshold T are selected as candidate (if no box meet this limit, the bounding box with the maximum value is selected). As can be seen in figure 6.3, it generates a lot of overlapping copies. That’s why, the final step of the localisation process is to discard small bounding boxes and overlapping ones (overlap higher than 30 %), keeping the ones with highest probabilities.

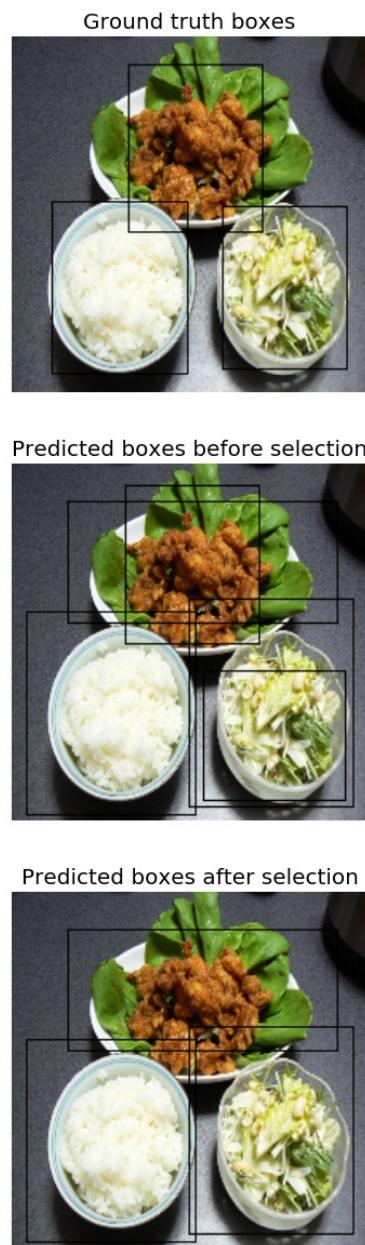

Figure 6.3: Segmentation process with: the bounding boxes (top), the candidate bounding boxes (middle), the proposed bounding boxes after overlapping suppression (bottom)

6.3 Food recognition

6.3.1 Histograms and moments

The first feature descriptor used combined histograms of LBP and Color with color moments for each picture:

1. extract a 100-bin histogram of local binary pattern on the grayscale image
2. extract a 30-bin by 30-bin joint color histogram for the channel H and s of the HSV representation
3. extract the first two moments of the R, G, B, H, S and Gray channels
4. extract the 7 Hu moments

The feature vectors are then normalized to have all features centered around zero (mean equal to 0) and have unit variance (equal to 1).

Then, apply multiple classifiers:

- decision tree
- random forest (made up of 500 trees)
- SVM

Talk in result: show the best amelioration with hyperparameter (but in general it only improve it by one or two percents)

6.3.2 Bag of words

1. detection of keypoints using a dense grid (4 spaces)

2. descriptors: Root SIFT. Root SIFT is a simple variant of SIFT, presented in [36].

When the SIFT descriptors have been computed for each keypoints, we apply an element wise square root of the L1 normalized SIFT vectors

Then these feature vectors are clustered using the k-means algorithm to obtain a 1000-word codebook.

For each picture, we compute the histogram of occurrence counts of visual words.

This descriptor is used with the SVM classifier and additive χ -squared kernel

6.3.3 CNN as a Descriptor

As described in section 4, a CNN can be used as a feature descriptor. The pre-trained CNN was used for image recognition on ImageNet Challenge 2014 and presented in [37].

It is available ².

The model is an improved version of the 19-layer model used by the VGG team in the ILSVRC-2014 competition. As the CNN used for segmentation, it takes a 224×224 RGB picture.

The output of the layer just before the FC is used as a descriptor. Thus, each picture is described by a 4096 feature vectors.

6.4 Code

The code is freely available on Github³.

I'm using python 3.5.2 and its scientific stack based on Scipy [38]:

- Numpy [39] for N-dimensional array

³https://github.com/bnogaret/food_log

- Pandas [40] for the data structure
- Scikit-image [41] and opencv 3 [42] for some of the image processing algortihms
- Scikit-learn [43] for most of the machine learning and Caffe [44] for the CNN
- Matplotlib [45] for 2D graph generation
- Sphinx for the documentation

Chapter 7

Evaluation

7.1 Environment

All the code has been run on the “Astral” high performance computer of Cranfield’s university. The operating system is SUSE Linux Enterprise Server 11 (64 bits architecture), with a Linux 3 kernel.

The system is separated in login nodes and compute nodes. There are two “front-end” login nodes and they contain two Intel E5-2660 (Sandy Bridge - 8 cores) CPUs giving 16 CPU cores and have a total of 192 GB of shared memory. The login nodes enable the user to connect to the system and compile one’s program. There are 80 compute nodes, each node having two Intel E5-2660 (Sandy Bridge - 8 cores) CPUs. This is giving a total of 1280 available cores. Each compute node have at least accessed to 64 GB shared memory. Nodes are connected with InfinibandTM low-latency interconnect.

7.2 Segmentation metrics

To measure the precision of the localization / segmentation algorithm, we use the metrics as defined in [46]¹.

To be considered a correct detection, the **Intersection over Union** *IoU* between the predicted bounding box B_p and ground truth bounding box B_{gt} must exceed 50% by the formula:

$$IoU = \frac{area(B_p \cap B_{gt})}{area(B_p \cup B_{gt})}$$

To simplify the calculation, this formula can be rewritten as:

$$IoU = \frac{area(B_p \cap B_{gt})}{area(B_p) + area(B_{gt}) - area(B_p \cap B_{gt})}$$

Using this metric, we can compute the precision P , the recall R and the accuracy A given by:

$$P = \frac{T_p}{T_p + F_p}$$

$$R = \frac{T_p}{T_p + F_n}$$

$$A = \frac{T_p}{T_p + F_n + F_p}$$

with:

- T_p the number of true positives (the bounding boxes correctly localized)
- F_p the number of false positives (the predicted bounding boxes incorrectly local-

¹Information on the evaluation system can be found at http://host.robots.ox.ac.uk/pascal/VOC/voc2012/devkit_doc.pdf

ized)

- F_n the number of false negative (the ground truth bounding boxes not localized)

Note that given the convention from [46], if more than one predicted bounding box overlaps the same ground truth bounding box, only one will be considered as T_P , the rest will be F_P s.

7.3 Cross validation

Cross validation is a technique used to assert the generalization to a new dataset of the different metrics used.

A common type of cross validation is the k-fold cross validation. In this method, the original sample is randomly split into k partitions of equal sized. Of these generated subsamples, a single split is used for test set, the remaining are used as training data. This last task is repeated k times, each of the k partitions being used only once for testing. The k results can then be averaged to produce a single estimation (illustrated in figure 7.1)

The advantage of this method over repeated random sub-sampling is that all observations are used for both training and testing, each observation being used for testing exactly once.

10-fold cross-validation were used for all the presented results (the most common fold value that maximises the training set size).

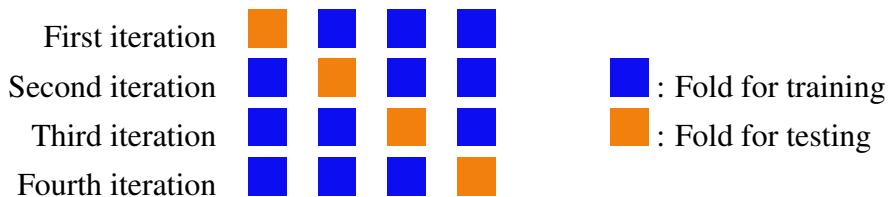

Figure 7.1: Illustration of 4-fold cross validation

7.4 Results

First, the localisation and classification processes were run independantly (using the ground truth bounding box for classification).

7.4.1 Food localisation

Metric (average)	My method	DCNN from [14]
Accuracy	73 %	60 %
Recall	74 %	80 %
Precision	79 %	70 %

Table 7.1: Average localisation accuracy result for UEC FOOD 256

The table 7.1 gathers the average accuracy, recall, precision of my localisation method using a DCNN pre-trained on salient object detection. In [14], the authors use fine-tuned pre-trained Deep Neural Network and obtain around 60 % of accuracy (using the same IoU over 50 %).

Compare to the found litterature, my method lead to a higher accuracy. It seems that the assumptions made to switch from a DCNN trained to detect food / non-food detection to salient object detection is founded.

For the result of the table 7.1, we use an IoU of 50 %. In Fig 7.2, we can see that the metrics' values are greatly influenced by the threshold choose for correctness (from 73 % of average accuracy with a threshold at 50 % to 0 % of accuracy for a thresholf of 100 %).

7.4.2 Classification

In [14], the authors use fine-tuned pre-trained Deep Neural Network and obtain 63 % accuracyon UEC FOOD-256.

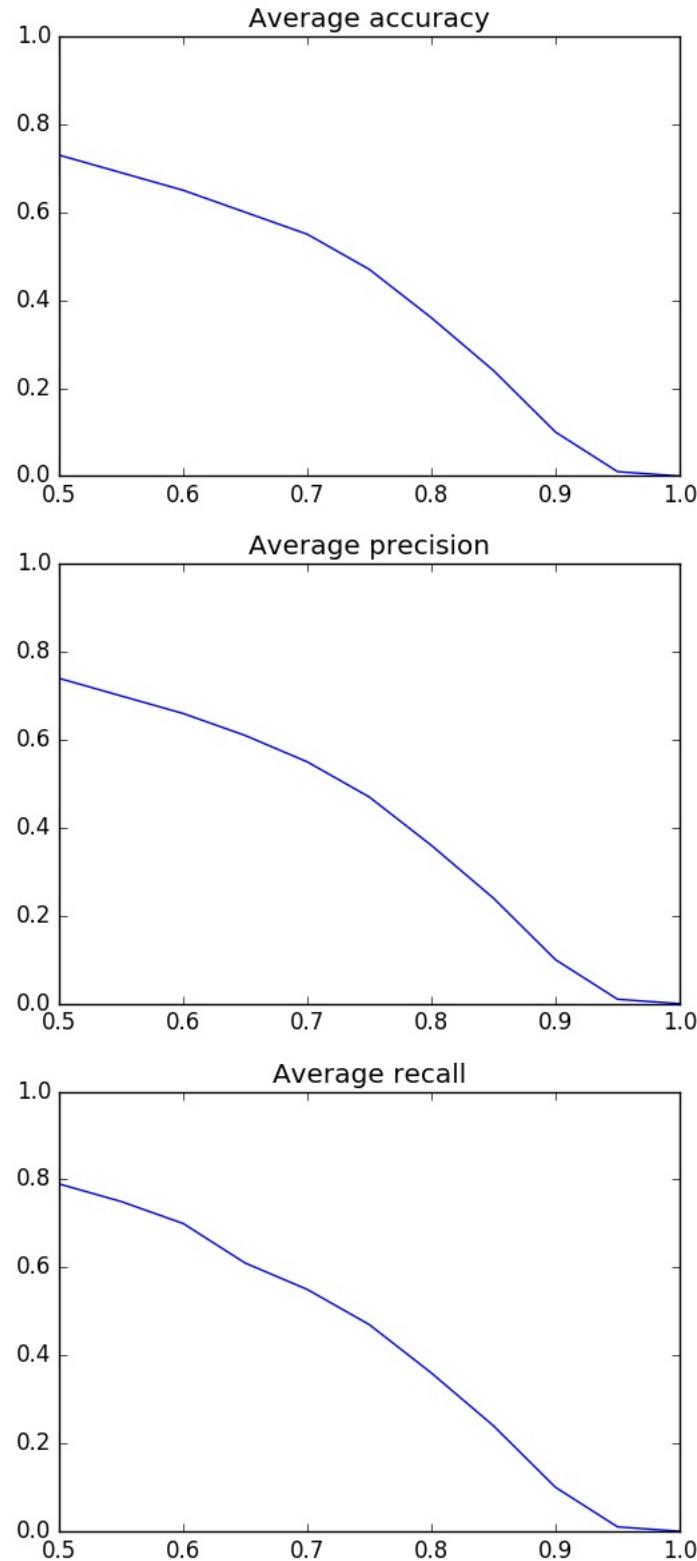

Figure 7.2: Curves of Accuracy over IoU (top), Precision over IoU (centre) and Recall over IoU (bottom)

Method	Average accuracy
CNN as descriptor + RF	40 %
BoW (1000 words)+ SVM with χ^2	10 %
LBP + color histograms and moments + Decision tree	5 %
LBP + color histograms and moments + SVM	11 %
LBP + color histograms and moments + RF	16 %
DCNN from [14]	63 %
DCNN from [12]	67 %

Table 7.2: Average classification accuracy result for UEC FOOD 256

Process	My method	DCNN from [14]
Overall	28 %	37 %
Localisation	74 %	60 %
Classification	38 %	60 %

Table 7.3: Average accuracy result for UEC FOOD 256

In [12], the authors use fine-tuned pre-trained Deep Neural Network and obtain 67 % accuracy on UEC FOOD-256.

7.4.3 Segmentation followed by classification

My classification is slightly less accurate as the bounding box is not as precise as the ground truth.

Using the segmentation and classification method with the highest accuracy, i.e. CNN Segmente + CNN feature descriptor + RF classifier

As can be seen in Fig 7.3 and 7.4, the best performing class is rice and the least one is tanmen. The possible explanations are:

- rice is the most represented food items in the dataset, maximising the size of the training sets (same for miso soup)
- rice has a specific texture and color that is relatively invariant to the condition

Figure 7.3: The five classes having the highest accuracy with (from the left to the right, starting from the highest accuracy) rice (98 %), miso soup (95 %), grilles pacific saury (94 %), hamburger (93 %), roll bread (90 %)

Figure 7.4: The five classes having the lowest accuracy with (from the left to the right, starting from the lowest accuracy) tanmen (0 %), Pork with lemon (0 %), clear soup (1 %), yellow curry (1 %), grilles eggplant (1 %)

- tanmen is a soup containing noodle and various vegetables. Thus, it can occur in different color, shape and size.
- there are numerous soups in the dataset and tanmen is often confused with them.

Process	My method	DCNN from [47]	DCNN from [11]
Overall	33 %	-	-
Localisation	67 %	60 %	-
Classification	50 %	-	72 %

Table 7.4: Average accuracy result for UEC FOOD 100

Figure 7.5: The six most confused classes (with from the left to the right, starting from the lowest accuracy) clear soup and miso soup (83 %), chicken rice and fried rice (54 %)

Chapter 8

Future work

One of the possible future area of work is using a more accurate feature descriptor and / or classifier. Compared to the litterature, my food recognition is rather low. Using a pre-trained DCNN for food recognition seems a promising tool.

It could be also interesting to use multiple segmentation method to combine them.

Then, it can be added the estimation part that includes a calorie evaluation or a simplified version based on MyPyramid or MyPlate and an application to take picture and visualize user's record.

Appendix A

Appendix

A.1 RGB to HSV

Assuming the RGB values have been normalised to be in $[0, 1]$, we have:

$$M = \max(R, G, B) \quad m = \min(R, G, B) \quad C = M - m$$

$$H = \begin{cases} 0 & \text{if } C = 0 \\ 60 \times \left[\frac{G-B}{C} \mod 6 \right] & \text{if } M = R \\ 60 \times \left[\frac{B-R}{C} + 2 \right] & \text{if } M = G \\ 60 \times \left[\frac{R-G}{C} + 4 \right] & \text{if } M = B \end{cases}$$

$$S = \begin{cases} 0 & \text{if } M = 0 \\ \frac{C}{M} & \text{otherwise} \end{cases}$$

$$V = M$$

A.2 HSV to RGB

The obtained R, G and B values are in $[0, 1]$ and calculated as such:

$$C = V \times S \quad X = C \times \left(1 - \left|\frac{H}{60} \bmod 2 - 1\right|\right) \quad m = V - C$$

$$(R', G', B') = \begin{cases} (C, X, 0) & 0 \leq H \leq 60 \\ (X, C, 0) & 60 \leq H \leq 120 \\ (0, C, X) & 120 \leq H \leq 180 \\ (0, X, C) & 180 \leq H \leq 240 \\ (X, 0, C) & 240 \leq H \leq 300 \\ (C, 0, X) & 300 \leq H \leq 360 \end{cases}$$

$$(R, G, B) = (R' + m, G' + m, B' + m)$$
